Abstract: The problem of lead toxicity originated in a private farm in El-Katta “Giza governorate”, due to ingestion of plant polluted with lead. About 8 out of 50 bull animals showed lead toxicity. The animal’s age was 6 months. The animals suffered from depression, pressing head against objects, dilatation of eye pupils, total blindness (in 2 cases) with normal light reflex in both eyes, edema in briskets, enteritis with bloody diarrhea and pupil dilatation. Also there were lacrimation, pale dirty mucous membrane and sunken eyes. Serum analysis from these animals revealed high lead concentration. In addition too, significant decrease in the levels of testosterone, LH, FSH PCV, haemoglobin, R.B.C.s and total proteins were also decreased. Highly degeneration of kidney and liver accompanied with elevation of AST, ALT, Urea, creatinine, cortisol, sodium and potassium. Moreover, Staphylococcus sp., S. epidermidis and S. Aeruginosa were isolated. We conclude that the cause of animals morbidity and mortality in this farm was not due to bacterial infections but due to lead toxicity and we can say that polluted environment, especially with lead, can cause severe harm to animal health, in addition to serious danger on human health, by eating food polluted with lead.

Key words: Lead toxicity in bull • environmental pollution • biochemical and microbial changes

INTRODUCTION

Lead is a major environmental pollutant and its toxicity continues to be a major public health problems and there is a growing consensus that lead cause toxic injury to human at a level of exposure that was considered to be safe only a decade ago. As the chronic exposure to lead, even at low levels, can result in slow progressive, in most of time, irreversible damage to haematopoetic, nervous and renal systems [1]. Recent researches predicted that high levels of toxic metals in scalp hair, due to environmental pollution, in addition to deficiency in trace metals, play a role in the development of heart diseases [2].

In recent years, research efforts are directed towards quantification of the impact of lead exposure on human health, particularly from environment. The diagnosis based on blood lead levels doesn’t always give an accurate estimate of total body burden of lead, so it’s important to detect sub cellular damage using reliable sensitive biomarkers [3]. Animals are very good indicator of the environmental pollution, as they inhabit the same space as humans and are exposed to the action of the same pollutants, for that reason, it’s appropriate and advantageous to evaluate the negative impact of the polluted environment by heavy metals and their influences load on human health by parallel evaluation of their load on animals [4, 5], so measuring of lead in blood animals [6], in cows and especially in lactating one, proved to be a good indicator of environmental contamination and also for food contamination from polluted animal [7].

MATERIALS AND METHODS

Animals: 8 young bull of 6 months old were used in the present study. They were obtained from a private farm in El-Katta “Giza governorate”. The animals suffered from depression, pressing head against objects, dilatation of eye pupils, total blindness (in 2 cases) with normal papillary light reflex in both eyes, edema in briskets, enteritis with bloody diarrhea and papillary dilatation. Also there were lacrimation, pale dirty mucous membrane and sunken eyes.

165
**Haematological studies:** Blood samples were collected from the jugular vein on EDTA as anticoagulant for determination of Hb, PFC, ESR, RBC's count and WBC's count, according to Jain [8].

**Biochemical and Hormonal studies:** The activities of aspartic aminotransferase (AST) and alanine aminotransferase (ALT) as well as cholesterol, urea and creatinine levels were determined according to the method of Varley et al. [9] by using commercial kits (Bio Merieux, France).

Total serum protein was estimated according to Drupt [10]. Serum cortisol was analyzed by a Gamma counter using 125 I cortisol radioimmunassay kit (Baxter Health Care Corporation USA) according to the method described by Pickering and Pottinger [11]. Potassium, Sodium and lead concentrations were determined by atomic absorption spectrophotometry.

**Bacteriological studies:** Swabs from internal organs (liver, kidney, intestine and lungs) were collected under aseptic condition. The inoculated plates were incubated at 37°C for 24-48 h. The suspected colonies were picked and purified by further subculturing after which they were stained with Gram stain, for further biochemical identifications, the subjected isolates were classified according to Buchman et al. [12] and Wilson and Miles [13].

**Soil Forage:** The lead content of the soil and forage was measured by atomic absorption according to the method of Rodrigues and Castellon [14].

**Statistical analysis:** The obtained data were subjected to the student t-test according to Gad and Well [15].

**RESULTS**

In the present study, haematological examination showed significant decrease in haemoglobin, PFC and RBC's count and significant increase was found in ESR and W.B.C's count in all animals (Table 1).

Biochemical results detected significant increase in AST, ALT, urea, creatinine, cortisol, sodium, potassium and lead (Table 2). While, there was significant decrease in total protein level (Table 2). Serum LH, F.S.H and testosterone hormones were significantly decreased (Table 3).

The lead content was found to be 293.72 ppm in the polluted soil and 164.3 ppm in forage (Table 4). Bacteriological results revealed that the most predominant isolated micro-organisms was **Streptococcus**, **S. epidermidis** and **S. Aureogentosa** (Table 5).
DISCUSSION

From our results, we noticed a decrease in the level of hemoglobin, PVC and R.B.C's count, owing to the fact that lead intoxiation causes a documented defect in haem synthesis. The results obtained agreed with several authors [8, 16] because lead pollution has an inhibitory effect on globin synthesis, inhibits iron to form haem and inhibits delta amino levulinic acid dehydratase in red cells.

Moreover, we can conclude that lead toxicity has dangerous effect on animals in the studied areas where the lead content of soil measured was about 293.73 ppm and in contaminated pasture was 164.3 ppm, the lead poisoning in the studied bull may be due to grazing this contaminated pasture which may be contamination by industrial wastes [17]. Hob and Kim [18] reported that, lead concentration in plants was 80-160 ppm and in soil was 100-300 ppm which was considered as toxic level. Referring to the FAO-WHC[19] recommendations, the acceptable daily lead intake is 0.05 ppm. and our finding agreed with that of Bryant and Rose [20]; Fayid and Abdallah [21] and Zaki et al. [22].

Bacterial microorganism e.g. Streptococcus sp, S. Epidermis and S. Auroginasa were isolated from internal organs, similar finding were reported by Fingold and Martin [23] and Ducan and Prasse [24] who stated that bacterial microorganism are present in animals and birds suffering from high pollution with lead due to immunological suppression.

Both clinical signs and ocular changes, which were observed in the present work, might be attributed to the toxic effect of lead on the C.N.S as mentioned by Krameller-Frochter, [25] and Schlerka [26], this toxic effect was characterized by severe cerebral disturbances leading to blindness in some cases which may be due to cerebrocortical oedema, or may be also due to associated optic neuritis and optic atrophy. We can concluded, that all the clinical symptoms reported in the studied bull might be due to acute lead intoxiation, as mentioned by Ozmen and Mor [27].

The biochemical results detected in Table 2, showed significant increase in urea and creatinine, which are indicative of abnormal kidney functions, agreed with those of Goswami and Gachhui [29].

The disturbed liver and kidney functions have been seen on the last stage of lead toxicity, this agree with Zaki et al. [22].

The hormonal results, detected in Table 3, showed significant decrease in L.H., F.S.H. and testosterone, which are affected in the early stages of lead poisoning [30, 31].

In conclusion lead toxicity cause atrophy of liver, kidney, gonads blindness, in addition to the locomotor disturbances. And the cause of animal morbidity and mortality in this farm was not due to bacterial infections but due to lead toxicity. We can also say that polluted environment, especially with lead, can cause severe harm to animal health, in addition to serious danger on human health, by eating food polluted with lead.

This work supported from internal project 10/8/5 (P.I. Dr. Moura S. Zaki) belonging to National Research Center, Dokki, Giza, Egypt.
