Department of Plant Biology and Plant Biotechnology, Chikkaiah Naicker College, Erode. (T.N.) India

**Abstract:** Identification and characterization of germplasm is an important link between the conservation and utilization of plant genetic resources. The present investigation was undertaken for identification and genetic variation within eight high yielding varieties of ginger through RAPD markers. A total of 55 distinct DNA fragments ranging from 0.5-2.4 Kb were amplified by using twelve selected primers. The cluster analysis indicated that the eight varieties formed two major clusters. The first major cluster had only one variety 'S-558' with 43% similarity with other seven varieties. Second major cluster having seven varieties and divided into two minor clusters. One minor cluster had six varieties (IISR-Varada, Suprabha, Suruchi, Suravi, Himagiri, IISR Mahima, IISR Rejatha) and other having only one variety 'Nadia'. The second minor cluster further divided into two sub-minor clusters. 'IISR Mahima' and 'Himagiri' had 78% similarity among themselves and 70% similarity with 'Suprabha' and 'IISR Rejatha'. 'Suprabha' and 'IISR Rejatha' were having 81% similarity among themselves. However, 'Suravi' had 64% similarity with 'Suprabha', 'IISR Rejatha', 'IISR Mahima' and 'Himagiri'. The present study showed the distant variation within the varieties. This investigation will help to breeders for ginger improvement program.

**Key words:** *Zingiber officinale* • Genetic variation • RAPD

### INTRODUCTION

*Zingiber officinales* Rosc. (ginger) of the family Zingiberaceae is an important tropical horticultural plant, values all over the world as a spices and for its medicinal properties. It is rich in secondary metabolite such as Oleoresin [1].

Breeding of ginger is seriously handicapped by poor flowering and seed set. It is propagated vegetatively through rhizome. The germplasm collections in clonal repositories are also seriously affected by fungal diseases. Taking into account the utility, the conservation of genetic diversity and building up of nuclear base populations is essential for improvement of ginger. The most important role of conservation is to preserve the genetic variation and evolutionary process in viable populations of ecologically and commercially viable varieties/ genotypes in order to prevent potential extinction.

Molecular markers have provided a powerful new tool for breeders to search for new sources of variation and to investigate genetic factors controlling quantitatively inherited traits. The molecular approach for identification of plant varieties/genotypes seems to be

more effective than traditional morphological markers because it allows direct access to the hereditary material and makes it possible to understand the relationships between plants [2, 3].

PCR-based molecular markers have been widely used in many plant species for identification, phylogenetic analysis, population studies and genetic linkage mapping [2]. The RAPD markers can also be used in the study of the genetic variability of species or natural populations [4, 5] and in the identification of genotypes [6-8].

In this present investigation, we report the identification and genetic variation among eight varieties of ginger by using RAPD markers.

### MATERIALS AND METHODS

**Collection of Plant Varieties:** Eight high yielding varieties (*Zingiber officinales* vars. IISR-Varada, Suprabha, Suruchi, Suravi, Himagiri, IISR Mahima, IISR Rejatha and Nadia) of ginger were collected from Tamilnadu Agricultural University, Coimbatore, India. The rhizomes were planted in the nursery bed for sprouting.

**Isolation of DNA:** The young leaves were used for DNA analysis. DNA was extracted from fresh leaves collected from nursery by using the cetyltrimethyl ammonium bromide (CTAB) method [9]. Approx. 20 mg of fresh leaves was ground to powder in liquid nitrogen using a mortar and pestle. The ground powder was transferred to a 50 ml centrifugation tube with 10 ml of CTAB buffer [2% (w/v) CTAB, 1.4 M NaCl, 20mM EDTA, 100mM Tris (tris(hydroxymethyl) aminomethane)-HCl, pH 8.0 and 0.2% (v/v) a-mercaptoethanol]. The homogenate was incubated at 60°C for 2 h, extracted with an equal volume of chloroform/isoamyl alcohol (24: 1 v/v) and centrifuged at 10,000-g for 20 min (Remi, C24BL, India). DNA was precipitated from the aqueous phase by mixing with an equal volume of isopropanol. After centrifugation at 10,000-g for 10 min, the DNA pellet was washed with 70% (v/v) ethanol, air-dried and resuspended in TE (10mM Tris-HCl, pH 8.0 and 0.1mM EDTA) buffer.

#### **Confirmation and Amplification of RAPD-PCR Analysis:**

DNA quantifications were performed by visualizing under UV light, after electrophoresis on 0.8% (w/v) agarose gel. The resuspended DNA was then diluted in TE buffer to 5m g/m l concentration for use in polymerase chain reaction (PCR).

### **RESULT AND DISCUSSION**

Forty decamer primers, corresponding to kits A, C, D and N from (Genei, India) were initially screened using one variety of ginger 'Nadia' to determine the suitability of each primer for the study. Primers were selected for further analysis based on their ability to detect distinct, clearly resolved and polymorphic amplified products within the species/ varieties. To ensure reproducibility, the primers generating no, weak, or complex patterns were discarded.

Polymerase chain reactions (PCR) with single primer were carried out in a final volume of 25ml containing 20 ng template DNA, 100m M of each deoxyribonucleotide triphosphate, 20 ng of decanucleotide primer (Genei, India), 1.5mM MgCl<sub>2</sub>, 1-Taq buffer [10mM Tris-HCl (pH 9.0), 50 mM KCl, 0.001% gelatin] and 0.5U Taq DNA polymerase (Genei, India).

Amplification was performed in a (Mygene thermal cycler) programmed for a preliminary 2 min denaturation step at 94°C, followed by 40 cycles of denaturation at 94°C for 20 s., annealing at 38°C for 30 s and extension at 72°C for 1 min, finally at 72°C for 10 min for RAPD amplification. Amplification products were separated alongside a molecular weight marker (1.0 kb plus ladder, Genei, India) by 1.2% agarose gel electrophoresis in

1-TAE (Tris acetate EDTA) buffer stained with ethidium bromide and visualized under UV light. Gel photographs were scanned through a Gel Doc System and the amplification product sizes were evaluated using the software Quantity one (BioRad, USA).

Data were recorded as presence (1) or absence (0) of band products from the photographic examination. Each amplification fragment was named by the source of the primer, the kit letter or number, the primer number and its approximate size in base pairs. Bands with similar mobility to those detected in the negative control, if any, were not scored. Similarity index was estimated using the formula, S-2 NAB/NA-NB [10]. Where, NAB is the number of amplified products common to both A and B. NA and NB correspond to number of amplified product in A and B respectively. The average of similarity matrices was used to generate a tree by UPGMA (unweighted pair-group method arithmetic average) using Non Leniar Dynamics, version 2006 [11].

The present study offers an optimization of primer screening for evaluation of genetic relationship among eight varieties of *Zingiber officinale* through RAPD analysis. The variety 'Surabhi' was used for screening primers obtained from different series for amplification by using polymerase chain reactions. The results showed that A-and N-series primers produced relatively more amplification fragments compared to other series of primers. The amplification generated by primers OPC-14, OPC-18 and OPC-04 produced small numbers of fragments by using the variety 'Nadia'. The primers OPN-09, OPN-10 and OPN-15 produced maximum number of DNA fragments; the size of the DNA fragments ranged from 0.5 to 2.0 base pairs. The primer OPA-19 amplified 4 fragments whereas, OPN-10 produced 5 bands in var. Nadia.

It was also noted that some primers did not show any amplification in some of the variety. The number of fragments varied from one series of primers to other series. The twenty-decamer primers produced good amplification of RAPD fragment ranging from 500 to 2400 base pairs. Subsequently, 12 primers were selected and used to analyze the genetic relationship among eight varieties of ginger through polymerase chain reaction.

The reproducibility of the amplification product was tested on DNA from three independent extractions of the varieties. Most of the amplification reactions were duplicated. Only bands that were consistently reproduced across amplifications were considered for the analysis.

Bands with the same mobility were considered as identical fragments, receiving equal values, regardless of their staining intensity. When multiple bands in a region were difficult to resolve, data for that region of the gel

Table 1: Total number of amplified fragments and number of polymorphic fragments generated by PCR using selected random decamers

Name of primer	Sequence of the primers	Total number amplified products	Number of polymorphic	Products Size range [kb]
OPA-02	5'-TGCCGAGCTG-3'	5	2	0.5-1.2
OPA-13	5'-CAGCACCCAC-3'	4	2	0.6-1.7
OPA-19	5'-CAAACGTCGG-3'	4	3	0.8-2.4
OPA-20	5'-GTTGCGATCC-3'	4	2	1.3-2.1
OPN-09	5'-TGCCGGCTTG-3'	6	3	60.5-1.6
OPN-10	5'-ACAACGTTGG-3'	6	3	0.7-1.5
OPN-15	5'-CAGCGACTGT-3'	6	3	0.8-2.0
OPN-20	5'-GGTGCTCCGT-3'	5	2	20.6-1.7
OPC-04	5'-CCGCATCTAC-3'	4	1	0.5-1.1
OPC-09	5'-CTCACCGTCC-3'	4	2	0.7-1.2
OPC-14	5'-TGCGTGCTTG-3'	3	1	0.5-1.6
OPC-18	5'-TGAGTGGGTG-3'	4	1	0.8-2.0

was not included in the analysis. As a result, twelve informative primers were selected and used to evaluate the degree of polymorphism within eight varieties of ginger. The selected primers generated distinctive products in the range of 0.5 to 2.4 Kb. The maximum and minimum number of bands was produced by the primers OPN-15 (6), OPN-10 (6), OPN-09 (6) and OPC-14 (3) respectively (Table 1).

A total number of 55 amplified fragments was scored across eight varieties of ginger for the selected primers and was used to estimate genetic relationships among themselves. Out of 55 fragments obtained, only 25 fragments (45.5%) were polymorphic. The pattern of RAPD produced by the primers OPA-19, OPN-10 and OPN-09 are shown in Figure 1. The profile generated by using OPN-10 is polymorphic. The genetic variation through RAPD markers has been highlighted in a number of medicinal plants [12-15].

The present results show the narrow variation within some of the varieties. The similarity matrix was obtained after multivariate analysis using Nei and Li's coefficient and is presented in Table 2. The matrix value was ranged from 0.34 to 0.74, with a mean

value of 0.54. The high matrix values indicated that there varieties were distantly related to each other.

Nayak et al [16] reported that there was high genetic variation among the 16 varieties of ginger. The high difference in gene diversity among varieties reveals the presence of strong genetic structure between them and thus significant differences exist in the genotypic diversity among themselves. The similarity matrix obtained in the present study was used to construct a dendrogram with the unweighted UPGMA method and resulted in their distant clustering in the dendrogram (Figure 2).

The dendrogram shows two major clusters. The first major cluster had only one variety 'IISR-Varada' with 43% similarity with other seven varieties. Second major cluster having seven varieties and again divided into two minor clusters. One minor cluster had six varieties ('Suprabha', 'IISR Rejatha', 'IISR Mahima', 'Himagiri', 'Suravi' and 'Suruchi) and other having only one variety 'Nadia'.

The second minor cluster further divided into two sub-minor clusters. One sub minor cluster had only one variety 'Suruchi'. Another sub-minor cluster having five varieties; 'IISR Mahima' and 'Himagiri' had 78% similarity

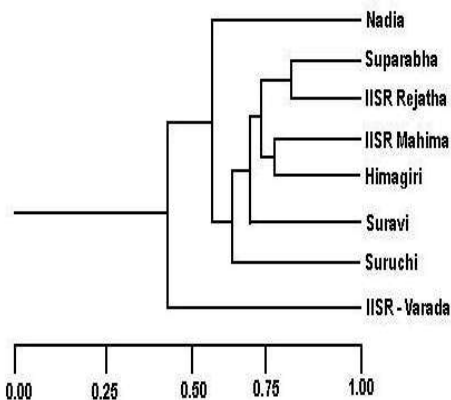

Fig. 2: Dendrogram of eight varieties of ginger generated by UPGMA based on RAPD markers.

among themselves and 70% similarity with 'Suprabha' and 'IISR Rejatha'. 'Suprabha' and 'IISR Rejatha' were having 81% similarity among themselves. 'Suravi' had 64% similarity with 'Suprabha', 'IISR Rejatha', 'IISR Mahima' and 'Himagiri'.

The differences in number of individuals estimated by RAPD markers in this study are similar to the result obtained by Rajaseger et al. [17] in RAPD studies of the *Ixora coccinea* and *I. javanica*. They also found that the taxa-specific RAPD bands could be utilized to

define the identification. The present findings include the identification and genetic variation within eight varieties of ginger.

The dendrogram shows the distant variation within the varieties. The genetic relation through RAPD markers provides a reliable method for identification of varieties than morphological characters. This investigation as an understanding of the level and partitioning of genetic variation within the varieties would provide an important input into determining efficient management strategies. The genetic variability in a gene pool is normally considered as being the major resource available to breeders for ginger improvement program.
