#### Abstract

In this paper, a stable method is proposed for solving time dependent partial differential equations in large domains using radial basis functions. In this new approach, a domain decomposition scheme is applied by using collocation points and thin plate splines. The scheme works in a similar fashion as finite difference methods. The merit of the proposed approach is that it is capable to reduce condition number of the matrices resulting from discretization of the equations and easily overcome the difficulty arising in solving complicated algebraic systems. The new method is applied to linear hyperbolic telegraph and nonlinear Klein-Gordon equations and the obtained results confirm the accuracy and efficiency of this method. The results of numerical experiments are presented with and without using domain decomposition method.

Key words: Collocation method . radial basis functions . partial differential equations . thin plate splines . domain decomposition

## INTRODUCTION

The Radial Basis Function (RBF) method has been actively used for solving Partial Differential Equations (PDEs) [1-3]. The RBF method for time dependent PDEs enjoy large advantages in accuracy over other flexible, but low order methods, such as finite differences, finite volumes and finite elements. However, RBF method shares the ease of implementation and flexibility of these lower order methods [4]. The traditional RBFs are globally defined functions which result in a full resultant coefficient matrix. In addition, in large domains, we require a large number of collocation points to get desirable accuracy, but we must also mention that the matrices which result from the discretization of the equations are usually ill-conditioned, in this case. This hinders the application of the RBFs to solve large domain problems due to severe ill-conditioning of the coefficient matrix.

In this article, to overcome this ill-conditioning conditioning problem in large domains and to get good accuracy in a stable structure, a new approach of the RBF method is constructed based on decomposition the domain to a few suitable subdomains. In this approach we use the finite-difference methods and employ the collocation method and approximate the solution directly by thin plate spline RBFs [5]. This structure without domain decomposition, used by Zerroukat et al. for solving heat transfer problem [6] and by Dehghan and Shokri for solving hyperbolic telegraph equation [2] and non-linear Klein-Gordon equation [7]. Here, we gain insight in one dimension before proceeding to
higher dimensions. The implementation and complexity of RBF methods in higher dimensions are essentially the same as in one dimension.

The layout of the article is as follows: In Section 2 we show that how the RBFs is used to approximate the solution. In Section 3 we apply the proposed method on time dependent PDEs in linear and nonlinear cases. The results of numerical experiments are presented in Section 4. Section 5 is dedicated to a brief conclusion. The numerical results are obtained by using MATLAB programming.

## RADIAL BASIS FUNCTION APPROXIMATION

In the interpolation of the scattered data using radial basis functions the approximation of a function $\mathrm{u}(\mathrm{x})$ at the centers $\mathrm{X}=\left\{\mathrm{x}_{1}, \ldots, \mathrm{x}_{\mathrm{N}}\right\}$, may be written as a linear combination of N RBFs; usually it takes the following form:

$$
\begin{equation*}
s_{u, X}(x)=\sum_{j=1}^{N} \alpha_{j} \phi\left(x-x_{j}\right)+\sum_{k=1}^{Q} \beta_{k} p_{k}(x) \tag{2.1}
\end{equation*}
$$

Here, Q denotes the dimension of the polynomial space $\pi_{\mathrm{m}-1}\left(\mathbb{R}^{\mathrm{d}}\right), \mathrm{p}_{1}, \ldots, \mathrm{p}_{\mathrm{Q}}$ denote a basis of $\pi_{\mathrm{m}-1}\left(\mathbb{R}^{\mathrm{d}}\right)$, $\mathrm{x}=\left\{\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{d}}\right\}, \mathrm{d}$ is the dimension of the problem, $\alpha$ 's and $\beta$ 's are coefficients to be determined, $\phi$ is the RBF. Some well-known RBFs are listed in Table 1.

To cope with additional degrees of freedom, the interpolation conditions

Middle-East J. Sci. Res., 11 (12): 1628-1635, 2012

Table 1: Some well-known functions that generate RBFs

| Name of function | Definition |
| :--- | :--- |
| Multiquadrics (MQ) | $\phi(x)=\sqrt{\mid \mathrm{x} \\|_{2}^{2}+\mathrm{c}^{2}}$ |
| Inverse multiquadrics (IMQ) | $\phi(\mathrm{x})=\left(\sqrt{\mid \mathrm{x} \\|_{2}^{2}+\mathrm{c}^{2}}\right)^{-1}$ |
| Gaussian (GA) | $\phi(\mathrm{x})=\exp \left(-\mathrm{c}\\|\mathrm{x}\\|_{2}^{2}\right)$ |
| Thin plate splines (TPS) | $\phi(\mathrm{x})=(-1)^{\mathrm{k}+1}\\|\mathrm{x}\\|_{2}^{2 \mathrm{k}} \log \\|\mathrm{x}\\|_{2}$ |
| Conical splines | $\phi(\mathrm{x})=\\|\mathrm{x}\\|_{2}^{2 \mathrm{k}+1}$ |

$$
\begin{equation*}
\mathrm{s}_{\mathrm{u}, \mathrm{X}}\left(\mathrm{x}_{\mathrm{j}}\right)=\mathrm{u}\left(\mathrm{x}_{\mathrm{j}}\right), \quad 1 \leq \mathrm{j} \leq \mathrm{N} \tag{2.2}
\end{equation*}
$$

are completed by the additional conditions

$$
\begin{equation*}
\sum_{\mathrm{j}=1}^{\mathrm{N}} \alpha_{\mathrm{j}} \mathrm{p}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{j}}\right)=0, \quad 1 \leq \mathrm{k} \leq \mathrm{Q} \tag{2.3}
\end{equation*}
$$

Solvability of this system is therefore equivalent to solvability of the system

$$
\left(\begin{array}{cc}
\mathrm{A}_{\phi, \mathrm{X}} & \mathrm{P}  \tag{2.4}\\
\mathrm{P}^{T} & 0
\end{array}\right)\binom{\alpha}{\beta}=\binom{\mathrm{u} \mid \mathrm{X}}{0}
$$

where

$$
\mathrm{A}_{\phi, \mathrm{X}}=\left(\phi\left(\mathrm{x}_{\mathrm{j}}-\mathrm{x}_{\mathrm{k}}\right)\right) \in \mathbb{R}^{\mathrm{N} \times \mathrm{N}} \text { and } \mathrm{P}=\left(\mathrm{p}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{j}}\right)\right) \in \mathbb{R}^{\mathrm{N} \times \mathrm{Q}}
$$

This last system is obviously solvable if the coefficient matrix on the left-hand side is invertible. Equation (2.1) can be written without the additional polynomial $\sum_{k=1}^{Q} \beta_{k} p_{k}(x)$. In that case, $\phi$ must be unconditionally positive definite to guarantee the solvability of the resulting system (e.g. Gaussian or inverse multiquadrics). However $\sum_{k=1}^{Q} \beta_{k} p_{k}(x)$ is usually required when $\phi$ is conditionally positive definite, i.e. when $\phi$ has a polynomial growth towards infinity. For instance, suppose $\phi$ is thin plate splines. Moreover, since these functions are globally supported, the interpolation matrix is full and may be very illconditioned for some RBFs.

In a similar representation as (2.1), for any linear partial differential operator $\mathcal{L}, \mathcal{L} \mathrm{u}$ may be approximated by [8]

$$
\begin{equation*}
\mathcal{L} \mathrm{u}(\mathrm{x}) \simeq \sum_{\mathrm{j}=1}^{\mathrm{N}} \alpha_{\mathrm{j}} \mathcal{L} \phi\left(\mathrm{x}-\mathrm{x}_{\mathrm{j}}\right)+\sum_{\mathrm{k}=1}^{\mathrm{Q}} \beta_{\mathrm{k}} \mathcal{L} \mathrm{p}_{\mathrm{k}}(\mathrm{x}) \tag{2.5}
\end{equation*}
$$

We use the thin plate spline RBFs in our method. The reason is that it has been shown by Franke [9], that MQ and thin plate spline give the most accurate results for scattered data approximations. Furthermore, the accuracy of the MQ method depends on a shape parameter and as yet there is no mathematical theory about how to choose its optimal value. Hence, most
applications of the MQ use experimental tuning parameters or expensive optimization techniques to evaluate the optimum shape parameter [10]. While the thin plate spline method gives good agreement without requiring such additional parameters and is based on sound mathematical theory [11].

$$
\phi(\mathrm{x})=(-1)^{\mathrm{k}+1}\left\|\left.\mathrm{x}\right|_{2} ^{2 \mathrm{k}} \log \right\| \mathrm{x} \|_{2}, \mathrm{k} \in \mathbb{N}
$$

from $\mathbb{R}^{\mathrm{d}}$ to $\mathbb{R}$ that generates thin plate spline RBFs is conditionally positive definite of order $\mathrm{m}=\mathrm{k}+1$, [12]. Since $\phi$ is $C^{2 k-1}$ continuous, a higher-order thin plate spline must be used, for higher-order partial differential operators.

To avoid problems at $x=0($ since $\log (0)=-\infty)$, we implement

$$
\phi(x)=(-1)^{3}\| \|\left\|_{2}^{3} \log \right\|\| \|\left\|_{2}\right\| \mathbb{N} \boldsymbol{x}_{\text {for } k}=2
$$

Definition 1: The points

$$
\mathrm{X}=\left\{\mathrm{x}_{1}, \ldots, \mathrm{x}_{\mathrm{N}}\right\} \subseteq \mathbb{R}^{\mathrm{d}} \text { with } \mathrm{N} \geq \mathrm{Q}=\operatorname{dim} \pi_{\mathrm{m}}\left(\mathbb{R}^{\mathrm{d}}\right)
$$

are called $\pi_{m-1}\left(\mathbb{R}^{d}\right)$-unisolvent if the zero polynomial is the only polynomial from $\pi_{\mathrm{m}}\left(\mathbb{R}^{\mathrm{d}}\right)$ that vanishes on all of them.

Theorem 1: Suppose that $\phi$ is conditionally positive definite of order $m$ and $X$ is a $\pi_{m-1}\left(\mathbb{R}^{d}\right)$-unisolvent set of centers. Then the system (2.4) is uniquely solvable.

## Proof: [12].

The numerical solution of PDEs by RBF methods is based on a scattered data interpolation problem which was reviewed in this section.

## IMPLEMENTATION OF THE NEW APPROACH

Linear case: Telegraph equation: Let us consider the following hyperbolic telegraph equation [2]:

$$
\begin{align*}
& \frac{\partial^{2} \mathrm{u}}{\partial \mathrm{t}^{2}}+\alpha \frac{\partial \mathrm{u}}{\partial \mathrm{t}}+\beta \mathrm{u}=\frac{\partial^{2} \mathrm{u}}{\partial \mathrm{x}^{2}}+\mathrm{f}(\mathrm{x}, \mathrm{t}) \\
& \mathrm{x} \in \Omega=[\mathrm{a}, \mathrm{~b}] \subset \mathbb{R}, \quad 0<\mathrm{t} \leq \mathrm{T} \tag{3.1.1}
\end{align*}
$$

with initial conditions

$$
\begin{cases}u(x, 0)=g_{1}(x), & x \in O  \tag{3.1.2}\\ u_{t}(x, 0)=g_{2}(x), & x \in O\end{cases}
$$

and Dirichlet boundary condition

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=\mathrm{h}(\mathrm{x}, \mathrm{t}), \quad \mathrm{x} \in \partial \mathrm{O}, \quad 0<\mathrm{t} \leq \mathrm{T} \tag{3.1.3}
\end{equation*}
$$

where $\alpha$ and $\beta$ are known constant coefficients, $f, \mathrm{~g}_{1}, \mathrm{~g}_{2}$ and h are known functions and the function u is unknown. In this method, we decompose $\Omega$ into a few subdomains

$$
\Omega_{1}=\left[\mathrm{a}_{1}, \mathrm{~b}_{1}\right], \ldots, \Omega_{\mathrm{m}}=\left[\mathrm{a}_{\mathrm{m}}, \mathrm{~b}_{\mathrm{m}}\right]
$$

uniformly. Then, let us discretize (3.1.1) according to the following $\theta$-weighted scheme

$$
\begin{align*}
\frac{u(x, t+\delta t)-2 u(x, t)+u(x, t-\delta t)}{(\delta t)^{2}} & +\alpha \frac{u(x, t+\delta t)-u(x, t-\delta t)}{2 \delta t}=\theta\left[\nabla^{2} u(x, t+\delta t)-\beta u(x, t+\delta t)\right]  \tag{3.1.4}\\
& +(1-\theta)\left[\nabla^{2} u(x, t)-\beta u(x, t)\right]+f(x, t+\delta t)
\end{align*}
$$

where $\nabla$ is the gradient differential operator, $0 \leq \theta \leq 1$ and $\delta t$ is the time step size. Rearranging (3.1.4), by the notation $u^{\mathrm{n}}=\mathrm{u}\left(\mathrm{x}, \mathrm{t}^{\mathrm{n}}\right)$ where $\mathrm{t}^{\mathrm{n}}=\mathrm{t}^{\mathrm{n}-1}+\delta \mathrm{t}$, we obtain

$$
\begin{equation*}
\left(1+\frac{\alpha \delta \mathrm{t}}{2}+\beta \theta(\delta \mathrm{t})^{2}\right) \mathrm{u}^{\mathrm{n}+1}-\theta(\delta \mathrm{t})^{2} \nabla^{2} u^{\mathrm{n}+1}=\left(2-\beta(1-\theta)(\delta \mathrm{t})^{2}\right) \mathrm{u}^{\mathrm{n}}+(1-\theta)(\delta \mathrm{t})^{2} \nabla^{2} u^{\mathrm{n}}+\left(\frac{\alpha \delta \mathrm{t}}{2}-1\right) \mathrm{u}^{\mathrm{n}-1}+(\delta \mathrm{t})^{2} \mathrm{f}^{\mathrm{n}+1} \tag{3.1.5}
\end{equation*}
$$

$\mathrm{u}_{\mathrm{k}}\left(\mathrm{x}, \mathrm{t}^{\mathrm{n}}\right)$, i.e., solution in $\mathrm{x} \in \Omega_{\mathrm{k}}$ and $\mathrm{t}=\mathrm{t}^{\mathrm{n}}$, can be approximated by

$$
\begin{equation*}
\mathrm{u}_{\mathrm{k}}^{\mathrm{n}}(\mathrm{x}) \simeq \sum_{\mathrm{j}=1}^{\mathrm{N}-3} \lambda_{\mathrm{k}, \mathrm{j}}^{\mathrm{n}} \phi\left(\mathrm{x}-\mathrm{x}_{\mathrm{k}, \mathrm{j}}\right)+\lambda_{\mathrm{k}, \mathrm{~N}-2}^{\mathrm{n}} \mathrm{x}^{2}+\lambda_{\mathrm{k}, \mathrm{~N}-1}^{\mathrm{n}} \mathrm{x}+\lambda_{\mathrm{k}, \mathrm{~N}}^{\mathrm{n}}, \quad \mathrm{k}=1, \ldots, \mathrm{~m} \tag{3.1.6}
\end{equation*}
$$

Let

$$
\left\{\mathrm{x}_{\mathrm{k}, \mathrm{j}}\right\}_{\mathrm{j}=1}^{\mathrm{N}-3}, \mathrm{k}=1, \ldots, \mathrm{~m}
$$

be a set of N-3 scattered nodes in $\Omega_{\mathrm{k}}$. Here, we take the Chebyshev-Gauss-Lobatto nodes in $\Omega_{\mathrm{k}}$ as follows:

$$
\begin{equation*}
\mathrm{x}_{\mathrm{k}, \mathrm{j}}=\frac{\mathrm{b}_{\mathrm{k}}-\mathrm{a}_{\mathrm{k}}}{2}\left(\cos \left(\frac{(\mathrm{j}-1) \pi}{\mathrm{N}-4}\right)\right)+\frac{\mathrm{b}_{\mathrm{k}}+\mathrm{a}_{\mathrm{k}}}{2}, \mathrm{k}=1, \ldots, \mathrm{~m}, \mathrm{j}=1, \ldots, \mathrm{~N}-3 \tag{3.1.7}
\end{equation*}
$$

Now, to determine the coefficients

$$
\left(\lambda_{\mathrm{k}, \mathrm{j}}\right)_{\mathrm{j}=1}^{\mathrm{N}}, \mathrm{k}=1, \ldots, \mathrm{~m}
$$

in each step, the collocation method may be used. For this reason, we put (3.1.6) into (3.1.5) in every subdomains $\Omega_{\mathrm{k}}$. Then by substituting collocation points $\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{j}=1,2, \ldots, \mathrm{~N}-4$ into obtained equation, we have

$$
\begin{align*}
& \left(1+\frac{\alpha \delta t}{2}+\beta \theta(\delta t)^{2}\right) u_{k}\left(x_{k, j}, t^{n+1}\right)-\left.\theta(\delta t)^{2} \nabla^{2} u_{k}\left(x, t^{n+1}\right)\right|_{x=x_{k, j}}=\left(2-\beta(1-\theta)(\delta t)^{2}\right) u_{k}\left(x_{k, j}, t^{n}\right)+ \\
& \left.(1-\theta)(\delta t)^{2} \nabla^{2} u_{k}\left(x, t^{n}\right)\right|_{x=x_{k, j}}+\left(\frac{\alpha \delta t}{2}-1\right) u_{k}\left(x_{k, j}, t^{n-1}\right)+(\delta t)^{2} f\left(x_{k, j}, t^{n+1}\right), \quad \begin{array}{l}
k=1, \ldots, m \\
j=2, \ldots, N-4
\end{array} \tag{3.1.8}
\end{align*}
$$

The additional conditions due to (2.3) are written as:

$$
\begin{equation*}
\sum_{j=1}^{N-3} \lambda_{k, j}^{n+1}=\sum_{j=1}^{N-3} \lambda_{k, j}^{n+1} x_{k, j}=\sum_{j=1}^{N-3} \lambda_{k, j}^{n+1} x_{k, j}^{2}=0, \quad k=1, \ldots, m \tag{3.1.9}
\end{equation*}
$$

For $\alpha_{1} \in \Omega_{1}$ and $b_{m} \in \Omega_{\mathrm{m}}$, we have the boundary conditions as follows:

$$
\begin{gather*}
\sum_{j=1}^{N-3} \lambda_{1, j}^{n+1} \phi\left(a_{1}-x_{1, j}\right)+\lambda_{1, N-2}^{n+1} a_{1}^{2}+\lambda_{1, N-1}^{n+1} a_{1}+\lambda_{1, N}^{n+1}=h\left(a_{1}, t^{n+1}\right)  \tag{3.1.10}\\
\sum_{j=1}^{N-3} \lambda_{m, j}^{n+1} \phi\left(b_{m}-x_{1, j}\right)+\lambda_{m, N-2}^{n+1} b_{m}^{2}+\lambda_{m, N-1}^{n+1} b_{m}+\lambda_{m, N}^{n+1}=h\left(b_{m}, t^{n+1}\right) \tag{3.1.11}
\end{gather*}
$$

To achieve a smooth solution on common boundary points from adjacent subdomains, the solutions in adjacent subdomains are imposed to reach the same amount and derivative in their common boundary points. Thus, we have

$$
\begin{align*}
\sum_{j=1}^{N-3} \lambda_{i-1, j}^{n+1} \phi\left(a_{i}-x_{i-1, j}\right) & +\lambda_{i-1, N-2}^{n+1} a_{i}^{2}+\lambda_{i-1, N-1}^{n+1} a_{i}+\lambda_{i-1, N}^{n+1} \\
& =\sum_{j=1}^{N-3} \lambda_{i, j}^{n+1} \phi\left(a_{i}-x_{i-1, j}\right)+\lambda_{i, N}^{n+1} a_{i}^{2}+\lambda_{i, N-1}^{n+1} a_{i}+\lambda_{i, N}^{n+1}, i=2, \ldots, m
\end{aligned} \begin{aligned}
\left.\sum_{j=1}^{N-3} \lambda_{i-1, j}^{n+1} \frac{d}{d x} \phi\left(x-x_{i-1, j}\right)\right|_{x=a_{i}} & +2 \lambda_{i-1, N-2}^{n+1} a_{i}+\lambda_{i-1, N-1}^{n+1}  \tag{3.1.12}\\
& =\sum_{j=1}^{N-3} \lambda_{i, j}^{n+1} \frac{d}{d x} \phi\left(x-x_{i-1, j}\right) \downarrow_{l=a_{i}}+2 \lambda_{i, N-2}^{n+1} a_{i}+\lambda_{i, N-1}^{n+1}, \quad i=2, \ldots, m \tag{3.1.13}
\end{align*}
$$

Equations (3.1.8)-(3.1.13) lead to a linear system of $m \mathrm{~N}$ equations with mxN unknowns. We use the LU factorization to the coefficient matrix and use this factorization in our algorithm. For $n=0$, the Eq. (3.1.8) has the following form

$$
\begin{align*}
& \left(1+\frac{\alpha \delta t}{2}+\beta \theta(\delta t)^{2}\right) \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{1}\right)-\left.\theta(\delta \mathrm{t})^{2} \nabla^{2} \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}, \mathrm{t}^{1}\right)\right|_{\mathrm{x}=\mathrm{x}_{\mathrm{k}, \mathrm{j}}}=\left(2-\beta(1-\theta)(\delta \mathrm{t})^{2}\right) \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{0}\right)+  \tag{3.1.14}\\
& \left.(1-\theta)(\delta \mathrm{t})^{2} \nabla^{2} \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}, \mathrm{t}^{0}\right)\right|_{\mathrm{x}=\mathrm{x}_{\mathrm{k}, \mathrm{j}}}+\left(\frac{\alpha \delta \mathrm{t}}{2}-1\right) \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{-1}\right)+(\delta \mathrm{t})^{2} \mathrm{f}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{1}\right), \begin{array}{l}
\mathrm{k}=1, \ldots, \mathrm{~m} \\
j=2, \ldots, \mathrm{~N}-4
\end{array}
\end{align*}
$$

Through initial conditions, we know that:

$$
\begin{equation*}
u_{k}\left(x, t^{0}\right)=g_{1}(x), \quad x \in O_{k} \tag{3.1.15}
\end{equation*}
$$

To approximate $u_{k}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{-1}\right)$ the second initial condition can be used. For this purpose we discretize the second initial condition as

$$
\begin{equation*}
\frac{\mathrm{u}_{\mathrm{k}}\left(\mathrm{x}, \mathrm{t}^{1}\right)-\mathrm{u}_{\mathrm{k}}\left(\mathrm{x}, \mathrm{t}^{-1}\right)}{2 \delta \mathrm{t}}=\mathrm{g}_{2}(\mathrm{x}), \quad \mathrm{x} \in \mathrm{O}_{\mathrm{k}} \tag{3.1.16}
\end{equation*}
$$

Thus, we have

$$
\begin{align*}
& \left(1+\frac{\alpha \delta \mathrm{t}}{2}+\beta \theta(\delta \mathrm{t})^{2}\right) \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{1}\right)-\left.\theta(\delta \mathrm{t})^{2} \nabla^{2} \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}, \mathrm{t}^{1}\right)\right|_{\mathrm{x}=\mathrm{x}_{\mathrm{k}, \mathrm{j}}}=\left(2-\beta(1-\theta)(\delta \mathrm{t})^{2}\right) \mathrm{g}_{1}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}\right)+ \\
& \left.(1-\theta)(\delta \mathrm{t})^{2} \nabla^{2} \mathrm{~g}_{1}(\mathrm{x})\right|_{\mathrm{x}=\mathrm{x}_{\mathrm{k}, \mathrm{j}}}+\left(\frac{\alpha \delta \mathrm{t}}{2}-1\right)\left(\mathrm{u}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{1}\right)-2(\delta \mathrm{t}) \mathrm{g}_{2}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}\right)\right)+(\delta \mathrm{t})^{2} \mathrm{f}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{1}\right), \begin{array}{l}
\mathrm{k}=1, \ldots, \mathrm{~m} \\
\mathrm{j}=2, \ldots, \mathrm{~N}-4
\end{array} \tag{3.1.17}
\end{align*}
$$

At other steps, no problems will be confronted and the solutions obtained from the two previous steps are used for the next step.
Nonlinear case: Klein-Gordon equation: Let us consider the following one-dimensional nonlinear Klein-Gordon equation [7]:

$$
\begin{equation*}
\frac{\partial^{2} u}{\partial t^{2}}+\alpha \frac{\partial^{2} u}{\partial x^{2}}+\beta u+\gamma u^{k}=f(x, t), \quad x \in O=[a, b] \subset \mathbb{R}, \quad 0<t \leq T \tag{3.2.1}
\end{equation*}
$$

with initial conditions

$$
\begin{cases}\mathrm{u}(\mathrm{x}, 0)=\mathrm{g}_{1}(\mathrm{x}), & \mathrm{x} \in \mathrm{O}  \tag{3.2.2}\\ \mathrm{u}_{\mathrm{t}}(\mathrm{x}, 0)=\mathrm{g}_{2}(\mathrm{x}), & \mathrm{x} \in \mathrm{O}\end{cases}
$$

and Dirichlet boundary condition

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=\mathrm{h}(\mathrm{x}, \mathrm{t}), \quad \mathrm{x} \in \partial \mathrm{O}, \quad 0<\mathrm{t} \leq \mathrm{T} \tag{3.2.3}
\end{equation*}
$$

where $\alpha, \beta$ and $\gamma$ are known constants. The $f, \mathrm{~g}_{1}, \mathrm{~g}_{2}$ and h are known functions and the function u is unknown. In the same way as mentioned in telegraph equation, we decompose $\Omega$ into a few subdomains

$$
\Omega_{1}=\left[\mathrm{a}_{1}, \mathrm{~b}_{1}\right], \ldots, \Omega_{\mathrm{m}}=\left[\mathrm{a}_{\mathrm{m}}, \mathrm{~b}_{\mathrm{m}}\right]
$$

uniformly and discretize (3.2.1) according to the following $\theta$-weighted schem

$$
\begin{align*}
\frac{\mathrm{u}(\mathrm{x}, \mathrm{t}+\delta \mathrm{t})-2 \mathrm{u}(\mathrm{x}, \mathrm{t})+\mathrm{u}(\mathrm{x}, \mathrm{t}-\delta \mathrm{t})}{(\delta \mathrm{t})^{2}}+\theta\left[\alpha \nabla^{2} \mathrm{u}(\mathrm{x}, \mathrm{t}+\delta \mathrm{t})+\beta \mathrm{u}(\mathrm{x}, \mathrm{t}+\delta \mathrm{t})\right]  \tag{3.2.4}\\
+(1-\theta)\left[\alpha \nabla^{2} \mathrm{u}(\mathrm{x}, \mathrm{t})+\beta \mathrm{u}(\mathrm{x}, \mathrm{t})\right]+\gamma(\mathrm{u}(\mathrm{x}, \mathrm{t}))^{\mathrm{k}}=\mathrm{f}(\mathrm{x}, \mathrm{t}+\delta \mathrm{t})
\end{align*}
$$

Rearranging (3.2.4), we obtain

$$
\begin{equation*}
\left(1+\beta \theta(\delta t)^{2}\right) u^{n+1}+\alpha \theta(\delta t)^{2} \nabla^{2} u^{n+1}=\left(2-\beta(1-\theta)(\delta t)^{2}\right) u^{n}+\alpha(1-\theta)(\delta t)^{2} \nabla^{2} u^{n}-\gamma(\delta t)^{2}\left(u^{n}\right)^{k}-u^{n-1}+(\delta t)^{2} f^{n+1} \tag{3.2.5}
\end{equation*}
$$

In every subdomains $\Omega_{\mathrm{k}}$, the collocation method is used by putting (3.1.6) into (3.2.5) and substituting collocation points $\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{j}=2, \ldots, \mathrm{~N}-4$ into obtained equation. Thus, we have

$$
\begin{align*}
& \left(1+\beta \theta(\delta t)^{2}\right) u_{k}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{\mathrm{n}+1}\right)+\left.\alpha \theta(\delta \mathrm{t})^{2} \nabla^{2} \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}, \mathrm{t}^{\mathrm{n}+1}\right)\right|_{\mathrm{x}=\mathrm{x}_{\mathrm{k}, \mathrm{j}}}=\left(2-\beta(1-\theta)(\delta \mathrm{t})^{2}\right) \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{\mathrm{n}}\right) \\
& +\left.\alpha(1-\theta)(\delta \mathrm{t})^{2} \nabla^{2} \mathrm{u}_{\mathrm{k}}\left(\mathrm{x}, \mathrm{t}^{\mathrm{n}}\right)\right|_{\mathrm{x}=\mathrm{x}_{\mathrm{k}, \mathrm{j}}}-\gamma(\delta \mathrm{t})^{2}\left(\mathrm{u}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{\mathrm{n}}\right)\right)^{\mathrm{k}}-\mathrm{u}_{\mathrm{k}}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{\mathrm{n}-1}\right)+(\delta \mathrm{t})^{2} \mathrm{f}\left(\mathrm{x}_{\mathrm{k}, \mathrm{j}}, \mathrm{t}^{\mathrm{n}+1}\right),{ }_{j=1, \ldots, \mathrm{~m}}^{\mathrm{k}=2, \ldots, \mathrm{~N}-4} \tag{3.2.6}
\end{align*}
$$

Again, we have the additional conditions (3.1.9), the boundary conditions (3.1.10) and (3.1.11) and the equations (3.1.12) and (3.1.13). Therefore, equations (3.2.6), (3.1.9)-(3.1.13) lead to a system of linear equations, which is solved using the LU factorization to the coefficient matrix in order to determine the coefficients

$$
\left(\lambda_{\mathrm{k}, \mathrm{j}}\right)_{\mathrm{j}=1}^{\mathrm{N}}, \mathrm{k}=1, \ldots, \mathrm{~m}
$$

in each step. For $\mathrm{n}=0$ the Eq. (3.2.6) has the following form

$$
\begin{align*}
& \left(1+\beta \theta(\delta t)^{2}\right) u_{k}\left(x_{k, j}, t^{1}\right)+\left.\alpha \theta(\delta t)^{2} \nabla^{2} u_{k}\left(x, t^{1}\right)\right|_{x=x_{k, j}}=\left(2-\beta(1-\theta)(\delta t)^{2}\right) u_{k}\left(x_{k, j}, t^{0}\right) \\
& +\left.\alpha(1-\theta)(\delta t)^{2} \nabla^{2} u_{k}\left(x, t^{0}\right)\right|_{x=x_{k, j}}-\gamma(\delta t)^{2}\left(u_{k}\left(x_{k, j}, t^{0}\right)\right)^{k}-u_{k}\left(x_{k, j}, t^{-1}\right)+(\delta t)^{2} f\left(x_{k, j}, t^{1}\right), \begin{array}{l}
k=1, \ldots, m \\
j=2, \ldots, N-4
\end{array} \tag{3.2.7}
\end{align*}
$$

according to relations (3.1.15) and (3.1.16), we have

$$
\begin{align*}
& \left(1+\beta \theta(\delta t)^{2}\right) u_{k}\left(x_{k, j}, t^{1}\right)+\left.\alpha \theta(\delta t)^{2} \nabla^{2} u_{k}\left(x_{,} t^{1}\right)\right|_{x=x_{k, j}}=\left(2-\beta(1-\theta)(\delta t)^{2}\right) g_{1}\left(x_{k, j}\right) \\
& +\left.\alpha(1-\theta)(\delta t)^{2} \nabla^{2} g_{1}(x)\right|_{x=x_{k, j}}-\gamma(\delta t)^{2}\left(g_{1}\left(x_{k, j}\right)\right)^{k}-\left(u_{k}\left(x_{k, j}, t^{1}\right)-2(\delta t) g_{2}\left(x_{k, j}\right)\right)+(\delta t)^{2} f\left(x_{k, j}, t^{1}\right), \begin{array}{l}
k=1, \ldots, m \\
j=2, \ldots, N-4
\end{array} \tag{3.2.8}
\end{align*}
$$

At other steps, no problems will be confronted and the solutions obtained from the two previous steps are used for the next step.

Remark: Although equations (3.1.4) and (3.2.4) are valid for any value of $\theta \in[0,1]$, we will use $\theta=1 / 2$ (the famous Crank-Nicolson scheme).

## NUMERICAL RESULTS

In this section, we present some numerical results to test the efficiency of the new scheme for solving time dependent partial differential equations.

Example 1: Consider the hyperbolic telegraph Eq. (3.1.1) with $\alpha=6$ and $\beta=2$ in the interval $\Omega$. The initial conditions are given by

$$
\begin{cases}u(x, 0)=g_{1}(x)=\sin (x), & x \in O \\ u_{t}(x, 0)=g_{2}(x)=-\sin (x), & x \in O\end{cases}
$$

and the analytical solution is given in [2] as

$$
\mathrm{u}(\mathrm{x}, \mathrm{t})=\sin (\mathrm{x}) \exp (-\mathrm{t})
$$

In this case

$$
f(x, t)=-2 \exp (-t) \sin (x)
$$

We extract the boundary function $h(x, t)$ from the exact solution. We solve this equation in different computational domains (Table 2). The RMS and the maximum errors of the obtained numerical results are achieved at $t=1$. The RMS and the maximum errors are defined as follow, respectively:

$$
\begin{gathered}
E^{2}=\sqrt{\frac{1}{N} \sum_{i=1}^{N}\left|u\left(x_{i}\right)-s\left(x_{i}\right)\right|^{2}} \\
E^{\infty}=\max _{1 \leq i \leq N}\left|u\left(x_{i}\right)-s\left(x_{i}\right)\right|
\end{gathered}
$$

where $u(x)$ is the exact solution, $s(x)$ is the approximate solution and $\left\{x_{i}\right\}_{i=1}^{N}$ are collocation points. In each row of the Table 2, we use the same number of collocation points. For example, in the first row, we use the algorithm without domain decomposition by 100 collocation points and with two subdomains by 50 collocation points in each subdomains.

The space-time graph of analytical solution is given in Fig. 1. We also demonstrate the space-time graph of absolute error with and without domain decomposition by the same number of collocation points in Fig. 2 and 3, respectively.

Example 2: Consider the nonlinear Klein-Gordon Eq. (3.2.1) with $\alpha=-1,(=0$. ( $=1$ and $\mathrm{k}=2$ in the interval (. The initial conditions are given by

$$
\begin{cases}u(x, 0)=g_{1}(x)=0, & x \in O \\ u_{t}(x, 0)=g_{2}(x)=\frac{1}{5} \cos (x), & x \in O\end{cases}
$$

The analytical solution is given as

Table 2: The RMS and the maximum errors, with and without domain decomposition, for example 1

| $\Omega$ | dt | Number of <br> subdomains | Number of collocation <br> points in each subdomains | $\mathrm{E}^{2}$ | Computational <br> Times $(\mathrm{s})$ |  |
| :--- | :---: | :---: | :---: | :--- | :--- | :--- |
| $[0,60]$ | 0.001 | 1 | 100 | 0.1526 | 0.7 |  |

|  |  | 6 | 30 | $3.1 \times 10^{-5}$ | $5.5 \times 10^{-5}$ | 2.6 |
| [0,80] | 0.005 | 1 | 160 | 0.3429 | 0.9440 | 0.8 |
|  |  | 4 | 40 | $1.1 \times 10^{-4}$ | $2.6 \times 10^{-4}$ | 1 |
| [0,50] | 0.0001 | 1 | 60 | Fail | Fail | - |
|  |  | 2 | 30 | $3.6 \times 10^{-4}$ | $8.9 \times 10^{-4}$ | 2.6 |

Table 4: The RMS and the Max errors, with and without domain decomposition, for Example 2 when $\mathrm{dt}=0.0001, \Omega=[0,50]$

| Number of subdomains | Number of collocation points in each subdomains | $\mathrm{E}^{2}$ | $\mathrm{E}^{\infty}$ | Condition number |
| :--- | :---: | :---: | :---: | :---: |
| 1 | 20 | 0.0071 | 0.0172 | $2.9 \times 10^{15}$ |
|  | 30 | 0.0034 | 0.0061 | $4.3 \times 10^{15}$ |
|  | 40 | 0.0034 | 0.0104 | $5.7 \times 10^{15}$ |
| 2 | 50 | 0.0284 | 0.1006 | $7.1 \times 10^{15}$ |
| 4 | 30 | $3.6 \times 10^{-4}$ | $8.9 \times 10^{-4}$ | $3.4 \times 10^{14}$ |
| 8 | 30 | $4.5 \times 10^{-5}$ | $1.2 \times 10^{-4}$ | $1.6 \times 10^{13}$ |

Fig. 1: Space-time graph of the analytical solution up to $\mathrm{t}=1 \mathrm{~s}$, with $\mathrm{dt}=0.01$ and $\mathrm{dx}=0.01$, for Example 1

Fig. 2: Space-time graph of the absolute error up to $\mathrm{t}=1 \mathrm{~s}$, with two subdomains 60 collocation points in each subdomain) and $\mathrm{dt}=0.001$, for Example 1

$$
u(x, t)=\frac{1}{5} t \cos x
$$

For this case we have

$$
f(x, t)=\frac{t \cos x}{5}\left(1+\frac{1}{5} t \cos x\right)
$$

Fig. 3: Space-time graph of the absolute error up to $\mathrm{t}=1 \mathrm{~s}$, with $\mathrm{dt}=0.001$ on 100 collocation points, without domain decomposition, for Example 1

Fig. 4: Space-time graph of the analytical solution up to $\mathrm{t}=1 \mathrm{~s}$, with $\mathrm{dt}=0.01$ and $\mathrm{dx}=0.01$, for Example 2

We extract the boundary function $h(x, t)$ from the exact solution. Table 3 and 4, show the accuracy and efficiency of the proposed approach in different domains. As mentioned in Example 1, we use the same number of collocation points in each row of Table 3.

Fig. 5: Space-time graph of the absolute error up to $\mathrm{t}=1 \mathrm{~s}$, with two subdomains ( 60 collocation points in each subdomain) and $\mathrm{dt}=0.001$, for Example 2

Fig. 6: Space-time graph of the absolute error up to $t=$ 1 s , with $\mathrm{dt}=0.001$ on 120 collocation points, without domain decomposition, for Example 2

The space-time graph of analytical solution is given in Fig. 4. We also demonstrate the space-time graph of absolute error with and without domain decomposition by the same number of collocation points in Fig. 5 and 6, respectively.

## CONCLUSION

A major drawback of the RBF collocation method is that a large number of collocation points are required in order to obtain a desirable accuracy on large domains. This hinders the application of the RBFs to solve large domain problems due to severe illconditioning of the coefficient matrix. To overcome this difficulty, the domain was decomposed to a few suitable subdomains. For instance, the linear hyperbolic telegraph equation and the nonlinear Klein-Gordon equation were solved in different domains to demonstrate the effectiveness of the new approach. The
numerical results showed the high accuracy of the proposed scheme in this research in comparison with the classical method lacking domain decomposition. Extension of the proposed method to solve time dependent PDEs in high dimensions is the subject of a future research work.
