#### Abstract

This paper suggested a new method for constricting a new exact travelling wave solution nonlinear physical equations. A transformation and a general function for travelling wave are introduced, using the Maple, a general exact solution can be readily obtained. By suitable choice of the parameters, the obtained solution reduces to various solitary and periodic solutions. The generalized regularized long-wave equation, Camassa-Holm equation, nonlinear Fokker-Planck equation, generalized Burgers-Fisher equation are used as illustrative examples to show the effectiveness and convenience of the method. The proposed method can be used to solve another nonlinear physics problems.

Key words: Nonlinear physical equations . solitary and periodic solutions

## INTRODUCTION

As more and more problems in branches of modern mathematics, physics and other interdisciplinary science are described in terms of suitable nonlinear models, directly exploring explicit and exact solutions to nonlinear evolution equations plays a very important role in nonlinear science, particularly in nonlinear physics science. In the past several decades, both mathematicians and physicists have made significant progress in this direction.

Many effective methods [1-13] have been presented such as variational iteration method [6], homotopy perturbation method [3], Exp-function method [13] and others. A complete review on the field is available on [3].

In this paper, by introducing a transformation and selecting appropriate, we successfully find rich explicit and exact solutions of four famous and physically important nonlinear evolution equations namely, the generalized regularized long-wave (RLW) equation, the Camassa-Holm equation, nonlinear Fokker Planck (FP) equation and the generalized Burgers-Fisher equation

The rest of this paper is arranged as follows. In Section 2, we briefly describe the proposed method. In Section 3, as illustrative examples, we apply it to
solving four physically significant nonlinear evolution equations. Some conclusion are given in the last section.

## METHODOLOGY

For a given the nonlinear evolution equations, say, in two independent variables x and t

$$
\begin{equation*}
\mathrm{Q}\left(\mathrm{u}, \frac{\partial \mathrm{u}}{\partial \mathrm{t}}, \frac{\partial \mathrm{u}}{\partial \mathrm{x}}, \frac{\partial^{2} \mathrm{u}}{\partial^{2}}, \frac{\partial^{2} \mathrm{u}}{\partial \mathrm{x}^{2}}, \ldots . .\right)=0 \tag{1}
\end{equation*}
$$

The left hand side of Eq.(1) is a polynomial in terms of $u$ and its various partial derivatives. In order to solve Eq.(1), we use the transformation

$$
\begin{equation*}
\mathrm{u}=\mathrm{u}_{0}+\frac{\partial \mathrm{v}}{\partial \mathrm{x}}, \mathrm{v}=\frac{\partial \ln \mathrm{w}}{\partial \mathrm{x}}, \mathrm{w}=\mathrm{w}(\mathrm{y}), \mathrm{y}=\mathrm{y}(\mathrm{x}, \mathrm{t}) \tag{2}
\end{equation*}
$$

in which $w(y)$ and $y(x, t)$ are two functions.

It is known that Eq.(1) are nonlinear equation and that their solutions should contain the phase fracture (kx-wt).As a result, we straightforwardly choose the trial function $\mathrm{y}(\mathrm{x}, \mathrm{t})$ in the following form

$$
\begin{equation*}
y=e^{(k x-w t)} \tag{3}
\end{equation*}
$$

where k and w are the wave number and the angular frequency, respectively.
We Suggest another function $w(y)$ as:

$$
\begin{equation*}
w(y)=\left[a+y^{2}\right]^{n} \tag{4}
\end{equation*}
$$

where a and n are constants to be determined later.
In view of Eq.(2) along with Eq.(3) as well as Eq.(4), we have

$$
\begin{gather*}
\mathrm{v}=\frac{\partial \ln \mathrm{w}}{\partial \mathrm{x}}=\frac{2 \mathrm{nky}^{2}}{\left[\mathrm{a}+\mathrm{y}^{2}\right]}  \tag{5}\\
\mathrm{u}=\mathrm{u}_{0}+\frac{\partial \mathrm{v}}{\partial \mathrm{x}}=\mathrm{u}_{0}+\frac{4 \mathrm{ank}^{2} \mathrm{y}^{2}}{\left[\mathrm{a}+\mathrm{y}^{2}\right]^{2}} \tag{6}
\end{gather*}
$$

In what follows, let us describe the proposed method as follows. Firstly, substituting the above equations into Eq.(1) yields a set of algebraic equations with regard to the unknown variables n and a and equating the coefficients of all power of $y$ to zero. Secondly, by solving the obtained system of algebraic equation for $n$ and a with the aid of Maple, we obtain the unknown constants $n$ and a. Lastly, inserting $n$ into Eq.(6) and using Eq.(3) along with choosing $\mathrm{a}=1$ and a $=-1$, respectively, then many new exact travelling wave solution are obtained. In the following, we shall apply the technique stated above to solve four physically important nonlinear evolution equations as illustrative examples.

## NEW APPLICATIONS

The generalized regularized long-wave (RLW) equation: Let us first consider the generalized regularized long-wave equation [14] reads

$$
\begin{equation*}
u_{t}+u_{x}+\alpha\left(u^{p}\right)_{x}-\beta u_{x x t}=0 \tag{7}
\end{equation*}
$$

where p is a positive integer and $\alpha$ and $\beta$ are positive constants. Eq.(7) was first put forward as a model for small amplitude long waves on the surface of water in a channel by Peregine $[15,16]$ and later by Benjamin [17]. In physical situation such as unidirectional waves propagating in a water channel, long crested waves in near shore zones and many other, the generalized long wave (RLW) equation serves an alternative model to the KdV equation [18].

Our main goal is to solve Eq.(7) by means of the proposed method illustrated above. Substituting Eqs. (3-6) into Eq. (7) and collecting the coefficients of
powers of $y$ with the aid of the computerized symbolic computation of the powerful Maple, then setting each of the obtained coefficients to zero, give rise to a set of algebraic equations with respect to the unknown variables a and n as follows:

$$
\begin{align*}
& -8 n k^{2} a\left[w a^{2}-a^{2} k-2 \alpha k u_{0} a^{2}-8 \alpha n a^{2} k^{3}+44 \beta w a^{2} k^{2}\right]=0 \\
& -8 n k^{2} a\left[-w a+k a+2 \alpha k \mathrm{~b}_{\mathrm{a}}+8 \alpha \mathrm{nak}^{3}-44 \beta w \mathrm{k}^{2}\right]=0 \\
& -8 \mathrm{nk}^{2} a\left[-w+\mathrm{k}+2 \alpha \mathrm{ku}_{0}+4 \beta w k^{2}\right]=0 \tag{8}
\end{align*}
$$

In view of Eqs.(8), we have

$$
\begin{align*}
\mathrm{a}=\mathrm{a}, \mathrm{n}=\frac{6 \mathrm{w} \beta}{\alpha \mathrm{k}}, \mathrm{u}_{0} & =-\frac{1}{2} \frac{-\mathrm{w}+\mathrm{k}+4 \beta \mathrm{wk}^{2}}{\mathrm{k} \alpha}  \tag{9}\\
\mathrm{c} & =\frac{\mathrm{w}}{\mathrm{k}} \tag{10}
\end{align*}
$$

Inserting Eq.(9) into Eq.(6) and taking into account Eq.(3) and Eq.(10) simultaneously, we obtain the general travelling wave solution the regularized longwave equation (7) as follows

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=-\frac{1}{2} \frac{-\mathrm{w}+\mathrm{k}+4 \beta \mathrm{wk}^{2}}{\mathrm{k} \alpha}+\frac{24 \mathrm{kw} \beta \mathrm{e}^{2 \mathrm{k}(\mathrm{xet})}}{\alpha\left(\mathrm{a}+\mathrm{e}^{2 \mathrm{k}(\mathrm{x}-\mathrm{ct})}\right)^{2}} \tag{11}
\end{equation*}
$$

where three arbitrary constants a , w and k . Making use of the following identity

$$
\begin{equation*}
\frac{\mathrm{e}^{\mathrm{x}}}{\mathrm{e}^{2 \mathrm{x}}+1}=\frac{1}{2} \operatorname{sech} x \tag{12}
\end{equation*}
$$

and setting $\mathrm{a}=1$ in Eq.(11), we get the so-called belltype solitary wave solution to the regularized longwave Eq.(7) in the following form

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=-\frac{1}{2} \frac{-\mathrm{w}+\mathrm{k}+4 \beta \mathrm{wk}^{2}}{\mathrm{k} \alpha}+\frac{6 \mathrm{w} \beta \mathrm{k}}{\alpha} \operatorname{sech}^{2} \mathrm{k}(\mathrm{x}-\mathrm{ct}) \tag{13}
\end{equation*}
$$

Making use of the following identity

$$
\begin{equation*}
\frac{\mathrm{e}^{\mathrm{x}}}{\mathrm{e}^{2 \mathrm{x}}-1}=\frac{1}{2} \operatorname{csch} \mathrm{x} \tag{14}
\end{equation*}
$$

and setting $\mathrm{a}=-1$ in Eq.(11), we have the singular travelling wave solution to regularized long-wave equation (7) as follows

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=-\frac{1}{2} \frac{-\mathrm{w}+\mathrm{k}+4 \beta \mathrm{wk}^{2}}{\mathrm{k} \alpha}-\frac{6 \mathrm{w} \beta \mathrm{k}}{\alpha} \operatorname{csch} \mathrm{k}(\mathrm{x}-\mathrm{ct}) \tag{15}
\end{equation*}
$$

Making use of the following identity

$$
\begin{equation*}
\operatorname{sech}^{2} x=\frac{2}{\cosh 2 x+1} \tag{16}
\end{equation*}
$$

then Eq.(13) admits to the following

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=-\frac{1}{2} \frac{-\mathrm{w}+\mathrm{k}+4 \beta \mathrm{wk}^{2}}{\mathrm{k} \alpha}+\frac{12 \mathrm{wk} \beta}{\alpha} \frac{1}{\cosh 2 \mathrm{k}(\mathrm{x}-\mathrm{ct})+1} \tag{17}
\end{equation*}
$$

Making use of the following identity

$$
\begin{equation*}
\operatorname{csch}^{2} x=\frac{2}{\cosh 2 x-1} \tag{18}
\end{equation*}
$$

then Eq.(15) can be converted to

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=-\frac{1}{2} \frac{-\mathrm{w}+\mathrm{k}+4 \beta \mathrm{wk}^{2}}{\mathrm{k} \alpha}-\frac{12 \mathrm{wk} \beta}{\alpha} \frac{1}{\cosh 2 \mathrm{k}(\mathrm{x}-\mathrm{ct})-1} \tag{19}
\end{equation*}
$$

Let $\mathrm{k}=\mathrm{i} \mathrm{K}$, where i is the imaginary unit and K the constant and making use of the following identity

$$
\begin{equation*}
\operatorname{sech}(i x)=\sec (x), \operatorname{csch}(i x)=-i \csc (x) \tag{20}
\end{equation*}
$$

then Eq.(8) and Eq.(15) can be reduced to

$$
\begin{align*}
& u(x, t)=-\frac{1}{2} \frac{-w+i K-4 \beta w K^{2}}{i K \alpha}+\frac{12 i \mathrm{i} w \beta}{\alpha} \sec ^{2} K(x-c t)  \tag{21}\\
& u(x, t)=-\frac{1}{2} \frac{-w+i K-4 \beta w K^{2}}{i K \alpha}+\frac{12 i \mathrm{i} w \beta}{\alpha} \csc ^{2} K(x-c t) \tag{22}
\end{align*}
$$

which are two triangle function-type periodic wave solutions of the regularized long-wave (RLW) equation (7).

Camassa-Holm equation: A second interactive model is the Camassa-Holm equation [19] reads

$$
\begin{equation*}
\mathrm{u}_{\mathrm{t}}+2 \mathrm{pu}_{\mathrm{x}}-\mathrm{u}_{\mathrm{xxt}}+3 \mathrm{uu}_{\mathrm{x}}=2 \mathrm{u}_{\mathrm{x}} \mathrm{u}_{\mathrm{xx}}+\mathrm{uu}_{\mathrm{xxx}} \tag{23}
\end{equation*}
$$

Eq.(23) appeared first in a physical context as describing the shallow water approximation in invisible hydrodynamics [20, 21]. The variable $u(x, t)$ represents the fluid velocity in the horizontal direction $x$ and $p$ is a constant.

In the same manner, to solve Eq. (23) using the proposed method. Similarly, putting Eqs. (3-6) into Eq. (23) and collecting the coefficients of powers of $y$ with the aid of the computerized symbolic computation of the powerful Maple, then setting each of the obtained coefficients to zero, results in a system of overdetermined algebraic equations with regard to the unknown variables a and $n$ as:

$$
\begin{align*}
& -8 \mathrm{nk}^{2} \mathrm{a}\left[-\mathrm{w}+2 \mathrm{pk}-4 \mathrm{k}^{3} \mathrm{u}_{0}+4 \mathrm{wk}^{2}+3 \mathrm{ku}_{0}\right]=0 \\
& -8 \mathrm{nk}^{2} \mathrm{aa}^{2} 36 \mathrm{au}_{0} \mathrm{k}^{3}+6 \mathrm{pka}-36 \mathrm{wak}^{2}+12 \mathrm{nak}^{3} \\
& \left.+9 \mathrm{nak}^{3}+9 \mathrm{kau}_{0}-48 \mathrm{nak}^{5}-3 \mathrm{wa}\right]=0  \tag{24}\\
& -8 \mathrm{nk}^{2} \mathrm{a}_{2}\left[40 \mathrm{a}^{2} \mathrm{u}_{0} \mathrm{k}^{3}+4 \mathrm{pa}^{2} \mathrm{k}-40 \mathrm{k}^{2} \mathrm{wa}^{2}+12 \mathrm{a}^{2} \mathrm{nk}^{3}\right. \\
& \left.+6 \mathrm{ku}_{0} \mathrm{a}^{2}+336 \mathrm{na}^{2} \mathrm{k}^{5}-2 \mathrm{wa}^{2}\right]=0
\end{align*}
$$

Solving the system of algebraic equations obtained above using Maple, we have

$$
\begin{align*}
& \mathrm{a}=\mathrm{a}, \mathrm{n}=\frac{8(\mathrm{w}+\mathrm{pk})}{\mathrm{k}\left(-16 \mathrm{k}^{2}+3+16 \mathrm{k}^{4}\right)} \\
& \mathrm{u}_{0}=\frac{-\mathrm{w}+2 \mathrm{pk}+4 \mathrm{wk}^{2}}{\mathrm{k}\left(4 \mathrm{k}^{2}-3\right)}, \mathrm{c}=\frac{\mathrm{w}}{\mathrm{k}} \tag{25}
\end{align*}
$$

Inserting Eq.(25) into Eq.(6) and making use of Eq.(3), admits the following the general travelling wave solution to the Camassa-Holm equation (23)

$$
\begin{align*}
\mathrm{u}(\mathrm{x}, \mathrm{t}) & =\frac{-\mathrm{w}+2 \mathrm{pk}+4 \mathrm{wk}^{2}}{\mathrm{k}\left(4 \mathrm{k}^{2}-3\right)} \\
& +\frac{32(\mathrm{w}+\mathrm{pk}) \mathrm{kae}^{2 \mathrm{k}(\mathrm{x}-\mathrm{ct})}}{\left(-16 \mathrm{k}^{2}+3+16 \mathrm{k}^{4}\right)\left(\mathrm{a}+\mathrm{e}^{2 \mathrm{k}(\mathrm{x}-\mathrm{ct})}\right)^{2}} \tag{26}
\end{align*}
$$

With the aid of (12) and setting $a=1$ in Eq. (26), we obtain the so-called bell type solitary wave solution to the Camassa-Holm equation (23) as follows

$$
\begin{align*}
\mathrm{u}(\mathrm{x}, \mathrm{t}) & =\frac{-\mathrm{w}+2 \mathrm{pk}+4 \mathrm{wk}^{2}}{\mathrm{k}\left(4 \mathrm{k}^{2}-3\right)} \\
& +\frac{8(\mathrm{w}+\mathrm{pk}) \mathrm{k}}{\left(-16 \mathrm{k}^{2}+3+16 \mathrm{k}^{4}\right)} \operatorname{sech} \mathrm{k}(\mathrm{x}-\mathrm{ct}) \tag{27}
\end{align*}
$$

By means of Eq. (14) and setting $\mathrm{a}=-1$ in Eq.(26), we possess the singular travelling wave solution of the Camassa-Holm equation (23) as follows

$$
\begin{align*}
u(x, t) & =\frac{-w+2 p k+4 \mathrm{wk}^{2}}{k\left(4 k^{2}-3\right)} \\
& -\frac{8(w+p k) k}{\left(-16 k^{2}+3+16 k^{4}\right)} \operatorname{csch}^{2} k(x-c t) \tag{28}
\end{align*}
$$

Similarly, making use of the former two equalities (16) and (18), admits Eq.(27) and Eq.(29) to the following form

$$
\begin{align*}
\mathrm{u}(\mathrm{x}, \mathrm{t}) & =\frac{-\mathrm{w}+2 \mathrm{pk}+4 \mathrm{wk}^{2}}{\mathrm{k}\left(4 \mathrm{k}^{2}-3\right)} \\
& +\frac{16(\mathrm{w}+\mathrm{pk}) \mathrm{k}}{\left(-16 \mathrm{k}^{2}+3+16 \mathrm{k}^{4}\right)} \frac{1}{\cosh 2 \mathrm{k}(\mathrm{x}-\mathrm{ct})+1} \tag{29}
\end{align*}
$$

$$
\begin{align*}
\mathrm{u}(\mathrm{x}, \mathrm{t}) & =\frac{-\mathrm{w}+2 \mathrm{pk}+4 \mathrm{wk}^{2}}{\mathrm{k}\left(4 \mathrm{k}^{2}-3\right)} \\
& -\frac{16(\mathrm{w}+\mathrm{pk}) \mathrm{k}}{\left(-16 \mathrm{k}^{2}+3+16 \mathrm{k}^{4}\right)} \frac{1}{\cosh 2 \mathrm{k}(\mathrm{x}-\mathrm{ct})-1} \tag{30}
\end{align*}
$$

Similarly, making use of the previous identity (20),then Eq.(27) and Eq.(28) can be reduced to

$$
\begin{align*}
\mathrm{u}(\mathrm{x}, \mathrm{t}) & =\frac{-\mathrm{w}+2 \mathrm{ipK}-4 \mathrm{wK} \mathrm{~K}^{2}}{\mathrm{iK}\left(-4 \mathrm{~K}^{2}-3\right)}  \tag{31}\\
& +\frac{8(\mathrm{w}+\mathrm{ipK}) \mathrm{i} \mathrm{~K}}{\left(16 \mathrm{~K}^{2}+3+16 \mathrm{~K}^{4}\right)} \sec ^{2} \mathrm{~K}(\mathrm{x}-\mathrm{ct}) \\
\mathrm{u}(\mathrm{x}, \mathrm{t}) & =\frac{-\mathrm{w}+2 \mathrm{ipK}-4 \mathrm{wK} \mathrm{~K}^{2}}{\mathrm{iK}\left(-4 \mathrm{~K}^{2}-3\right)} \\
& -\frac{8(\mathrm{w}+\mathrm{ipK}) \mathrm{i} \mathrm{~K}}{\left(16 \mathrm{~K}^{2}+3+16 \mathrm{~K}^{4}\right)} \csc ^{2} \mathrm{~K}(\mathrm{x}-\mathrm{ct}) \tag{32}
\end{align*}
$$

which are two triangle function-type periodic wave solutions of the Camassa-Holm equation (23).

The nonlinear Fokker Planck (FP) equation: Consider the nonlinear Fokker-Planck (FP) equation [22] in the form

$$
\begin{equation*}
u_{t}=u_{x}+\lambda\left(u^{2}\right)_{x x}+D u_{x x} \tag{33}
\end{equation*}
$$

where D is the diffusion coefficient and $\lambda$ is constant. The nonlinear Fokker-Planck (FP) equation (33) which appears for the macroscopic of generalized Langevin equations [23, 24].

Inserting Eqs. (3-6) into Eq.(33) and collecting the coefficients of powers of $y$ with the aid of the computerized symbolic computation of the powerful Maple, then setting each of the obtained coefficients to zero, results in a system of over-determined algebraic equations with regard to the unknown variables a and $n$ as follows:

$$
\begin{align*}
& -8 \mathrm{nak}\left\{\mathrm{wa}^{2}+\mathrm{ka}^{2}+2 \mathrm{ka}^{2} \mathbf{u}_{0}+8 \mathrm{na}^{2} \mathrm{k}^{3}-6 \mathrm{Dka}^{2}{ }^{2}\right]=0 \\
& -8 \mathrm{nak}^{2}\left[-\mathrm{wa}-\mathrm{ka}-2 \mathrm{kau}_{0}-8 \mathrm{nak}^{3}-6 \mathrm{Dka}\right]=0 \\
& -8 \mathrm{nak}^{2}\left[-\mathrm{w}-\mathrm{k}-2 \mathrm{ku}_{0}+2 \mathrm{Dk}^{2}\right]=0 \tag{34}
\end{align*}
$$

Solving the system of algebraic equations obtained above, we obtain the following solutions

$$
\begin{equation*}
\mathrm{a}=\mathrm{a}, \mathrm{n}=-\frac{\mathrm{D}}{\mathrm{k}}, \mathrm{u}_{0}=\frac{1}{2} \frac{-\mathrm{w}-\mathrm{k}+2 \mathrm{Dk}^{2}}{\mathrm{k}} \tag{35}
\end{equation*}
$$

Substituting Eq.(35) into Eq.(6) and taking into consideration Eq. (3) and Eq. (10) simultaneously, we
obtain the following the exact travelling wave solution for the nonlinear Fokker-Planck equation (33)

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=\frac{1}{2} \frac{-\mathrm{w}-\mathrm{k}+2 \mathrm{Dk}^{2}}{\mathrm{k}}-\frac{4 \mathrm{kDae}^{2 \mathrm{k}(\mathrm{x}-\mathrm{ct})}}{\left(\mathrm{a}+\mathrm{e}^{2 \mathrm{k}(\mathrm{x}-\mathrm{ct})}\right)^{2}} \tag{36}
\end{equation*}
$$

Similarly making use the identity Eq. (12) and setting $\mathrm{a}=1$ in Eq.(33), we possess the so-called bell type solitary wave solution of the nonlinear FokkerPlanck equation (33) as follows

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=\frac{1}{2} \frac{-\mathrm{w}-\mathrm{k}+2 \mathrm{Dk}^{2}}{\mathrm{k}}-4 \mathrm{kD} \operatorname{sech}^{2} \mathrm{k}(\mathrm{x}-\mathrm{ct}) \tag{37}
\end{equation*}
$$

Making use of the identity Eq. (14) and setting $\mathrm{a}=-1$ in Eq. (36), we find the singular travelling wave solution for the nonlinear Fokker-Planck equation (33) in the following form

$$
\begin{equation*}
\mathrm{u}(\mathrm{x}, \mathrm{t})=\frac{1}{2} \frac{-\mathrm{w}-\mathrm{k}+2 \mathrm{Dk}^{2}}{\mathrm{k}}+4 \mathrm{kD} \operatorname{csch}^{2} \mathrm{k}(\mathrm{x}-\mathrm{ct}) \tag{38}
\end{equation*}
$$

With the aid of the two previous equalities (16) and (18),then Eq.(37) and Eq.(38) admits

$$
\begin{align*}
& \mathrm{u}(\mathrm{x}, \mathrm{t})=\frac{1}{2} \frac{-\mathrm{w}-\mathrm{k}+2 \mathrm{Dk}^{2}}{\mathrm{k}}-8 \mathrm{kD} \frac{1}{\cosh 2 \mathrm{k}(\mathrm{x}-\mathrm{ct})+1}  \tag{39}\\
& \mathrm{u}(\mathrm{x}, \mathrm{t})=\frac{1}{2} \frac{-\mathrm{w}-\mathrm{k}+2 \mathrm{Dk}^{2}}{\mathrm{k}}+8 \mathrm{kD} \frac{1}{\cosh 2 \mathrm{k}(\mathrm{x}-\mathrm{ct})-1} \tag{40}
\end{align*}
$$

Making use of the identity Eq. (20),then Eq.(37) and Eq.(38) can be reduced to

$$
\begin{align*}
& \mathrm{u}(\mathrm{x}, \mathrm{t})=\frac{1}{2} \frac{-\mathrm{w}-\mathrm{i} \mathrm{~K}-2 \mathrm{DK}^{2}}{\mathrm{iK}}-4 \mathrm{iKD} \mathrm{\sec }^{2} \mathrm{~K}(\mathrm{x}-\mathrm{ct})  \tag{41}\\
& \mathrm{u}(\mathrm{x}, \mathrm{t})=\frac{1}{2} \frac{-\mathrm{w}-\mathrm{i} \mathrm{~K}-2 \mathrm{DK}^{2}}{\mathrm{iK}}+4 i \mathrm{KD} \csc ^{2} \mathrm{~K}(\mathrm{x}-\mathrm{ct}) \tag{42}
\end{align*}
$$

which are two new triangle function-type periodic wave solutions of the nonlinear Fokker-Planck equation (33).

The generalized Burgers-Fisher equation: In this case we consider the generalized Burgers-Fisher equation [25] reads

$$
\begin{equation*}
\mathrm{u}_{\mathrm{t}}+\mathrm{p} \mathrm{u}^{\mathrm{r}} \mathrm{u}_{\mathrm{x}}-\mathrm{u}_{\mathrm{xx}}-\mathrm{qu}\left(1-\mathrm{u}^{\mathrm{r}}\right)=0 \tag{43}
\end{equation*}
$$

where p and q are real constants and $\mathrm{p} \neq 1$ is positive constants.

As stated before, inserting Eqs.(3-6) into Eq. (43) and collecting the coefficients of powers of $y$, give rise to a set of algebraic equations with respect to the unknown variables $a$ and $n$. Solving the over-determined system of algebraic equation by virtue of Maple, we find that

$$
\begin{gather*}
\mathrm{a}=\mathrm{a}, \mathrm{u}_{0}=1, \mathrm{n}=-\frac{\left(4 \mathrm{k}^{2}+\mathrm{q}\right)}{\mathrm{k}^{2}(3 \mathrm{q}-4 \mathrm{qk})}, \mathrm{w}=2 \mathrm{k}^{2}+\mathrm{pk}-\mathrm{q}  \tag{44}\\
\mathrm{c}=\frac{2 \mathrm{k}^{2}+\mathrm{pk}-\mathrm{q}}{\mathrm{k}} \tag{45}
\end{gather*}
$$

Substituting Eq.(44) into Eq.(6) and using Eq. (3), we get the general travelling wave solution to the generalized Buerger-Fisher equation (43) as follows

$$
\begin{equation*}
\left.\mathrm{u}(\mathrm{x}, \mathrm{t})=1-\frac{4 \mathrm{a}\left(4 \mathrm{k}^{2}+\mathrm{q}\right) \mathrm{e}^{2 \mathrm{k}(\mathrm{x}-\mathrm{ct})}}{(3 \mathrm{q}-4 \mathrm{pk})\left(\mathrm{a}+\mathrm{e}^{2 \mathrm{k}(x-\mathrm{ct})}\right.}\right)^{2} \tag{46}
\end{equation*}
$$

By means of the identities Eq.(12),Eq. (14) and setting $\mathrm{a}=1$ and $\mathrm{a}=-1$ into Eq.(46), we get the socalled bell-type solitary wave solutions of the generalized Burgers-Fisher equation (43) as

$$
\begin{align*}
& u(x, t)=1-\frac{\left(4 k^{2}+q\right)}{(3 q-4 p k)} \operatorname{sech}^{2} k(x-c t)  \tag{47}\\
& u(x, t)=1+\frac{\left(4 k^{2}+q\right)}{(3 q-4 p k)} \operatorname{csch} k(x-c t) \tag{48}
\end{align*}
$$

Knowing, Eq. (16) and Eq. (18), then Eq. (47) and Eq. (48), admits

$$
\begin{align*}
& u(x, t)=1-\frac{2\left(4 \mathrm{k}^{2}+q\right)}{(3 q-4 \mathrm{pk})} \frac{1}{\cosh 2 \mathrm{k}(\mathrm{x}-\mathrm{ct})+1}  \tag{49}\\
& \mathrm{u}(\mathrm{x}, \mathrm{t})=1+\frac{2\left(4 \mathrm{k}^{2}+\mathrm{q}\right)}{(3 \mathrm{q}-4 \mathrm{pk})} \frac{1}{\cosh 2 \mathrm{k}(\mathrm{x}-\mathrm{ct})-1} \tag{50}
\end{align*}
$$

By using Eq.(20), then Eq.(47) and Eq.(48) can be simplified as

$$
\begin{align*}
& u(x, t)=1-\frac{\left(-4 K^{2}+q\right)}{(3 q-4 i p K)} \sec ^{2} K(x-c t)  \tag{51}\\
& u(x, t)=1+\frac{\left(-4 K^{2}+q\right)}{(3 q-4 i p K)} \csc ^{2} K(x-c t) \tag{52}
\end{align*}
$$

which are two triangle function-type periodic wave solutions of the generalized Burgers-Fisher equation (43).

## CONCLUSION

In summary, many types of explicit and exact travelling wave solutions to four nonlinear evolution equations arising in physics are obtained.

The validity of this method has been tested by applying it successfully to the generalized regularized long-wave (RLW) equation, the Camassa-Holm equation, nonlinear Fokker Planck equation and the generalized Burgers-Fisher equation.

As a result, these new exact travelling wave solutions include the solitary wave solutions, the singular travelling wave solutions and the triangle function-type periodic wave solutions, are successfully presented by making use of our unified trial function method.

Finally, it is worthwhile to mention that the proposed method is straightforward, concise and it is a promising and powerful new method for other nonlinear evolution equations in physics.
